Whole genome sequence analysis of BT-474 using complete Genomics' standard and long fragment read technologies

Serban Ciotlos^{1†}, Qing Mao^{1†}, Rebecca Yu Zhang¹, Zhenyu Li², Robert Chin¹, Natali Gulbahce¹, Sophie Jia Liu¹, Radoje Drmanac^{1,2} and Brock A. Peters^{1,2*}

Abstract

Background: The cell line BT-474 is a popular cell line for studying the biology of cancer and developing novel drugs. However, there is no complete, published genome sequence for this highly utilized scientific resource. In this study we sought to provide a comprehensive and useful data set for the scientific community by generating a whole genome sequence for BT-474.

Findings: Five µg of genomic DNA, isolated from an early passage of the BT-474 cell line, was used to generate a whole genome sequence (114X coverage) using Complete Genomics' standard sequencing process. To provide additional variant phasing and structural variation data we also processed and analyzed two separate libraries of 5 and 6 individual cells to depths of 99X and 87X, respectively, using Complete Genomics' Long Fragment Read (LFR) technology.

Conclusions: BT-474 is a highly aneuploid cell line with an extremely complex genome sequence. This ~300X total coverage genome sequence provides a more complete understanding of this highly utilized cell line at the genomic level.

Keywords: Long Fragment Read, Complete Genomics, BT-474, BT474, Whole genome sequencing, Breast cancer

Data description

Utility of the dataset

The cell line BT-474 was isolated by Lasfargues et al. [1] in 1978, from a biopsy of invasive ductal carcinoma from a 60 year old Caucasian female. Since that time it has become one of the most heavily utilized cell lines for breast cancer research. At the time of writing, entering the search term “BT-474 OR BT474” into PubMed resulted in 973 unique articles. Surprisingly, the complete genome sequence of this cell line has yet to be published. In this paper, we fill that void in the collective scientific knowledge by providing high coverage whole genome data for BT-474.

Previous studies have shown that BT-474 has a modal number of chromosomes approximating tetraploidy, and

most of these chromosomes are covered with megabase-sized amplifications, deletions, and other structural rearrangements [2]. In an effort to provide better coverage of these complex rearranged regions, and to provide variant phasing and error correcting information, we generated high coverage libraries from long genomic DNA (~40 kb) using Long Fragment Read (LFR) technology [3, 4], and supplemented those libraries with a standard (STD) short mate pair library (~500 bp) [5] for a combined total coverage of over ~300X. We hope the freely available resource provided in this paper will benefit our understanding of the biology of cancer, and ultimately help to improve therapies for patients.

Library generation

DNA was isolated from low passage number BT-474 cells, procured from the American Type Culture Collection (ATCC, Manassas, VA, USA), using a

Table 1 BT-474 genome statistics

Metric	BT-474 STD	BT-474 LFR1	BT-474 LFR2
Fully called genome fraction	0.972	0.915	0.900
Fully called exome fraction	0.988	0.928	0.920
Gross mapping yield (Gb)	343	298	261
Both mates mapped yield (Gb)	306	217	171
Genome fraction with sequence coverage $\geq 5x$	0.997	0.981	0.978
Exome fraction with sequence coverage $\geq 5x$	0.999	0.980	0.980
SNV total count	3,241,932	2,856,624	2,890,506
Homozygous SNV count	1,531,723	1,382,653	1,241,444
Heterozygous SNV count	1,635,402	1,195,290	1,239,735
Het/Hom ratio	1.07	0.86	1.00
ENA sample accession number	ERS823996	ERS823998	ERS823997

STD and LFR libraries were mapped to the NCBI reference genome build 37. An explanation of the genome statistics are as follows: fully called genome fraction, the fraction of the genome for which both alleles at each position are confidently called; fully called exome fraction, the fraction of the coding part of the genome for which both alleles are confidently called; gross mapping yield (Gb), the number of gigabases of read data that can be mapped to NCBI reference genome build 37; both mates mapped yield (Gb), the number of gigabases of read data where both arms of a mate pair can be mapped to NCBI reference genome build 37; genome fraction with sequence coverage $\geq 5x$, fraction of the genome with at least 5 reads covering a single position; exome fraction with sequence coverage $\geq 5x$, fraction of the coding genome with at least 5 reads covering a single position; SNV total count, the total number of single nucleotide variants called in each library; homozygous SNV count, the total number of homozygous variants called in each library; heterozygous SNV count, the total number of heterozygous variants called in each library; Het/Hom ratio, the ratio of heterozygous variants over homozygous variants (this number is typically around 1.6 for a Caucasian genome); ENA sample accession number, the European Nucleotide Archive accession number to locate the raw read data for each library

RecoverEase dialysis kit (Agilent, Santa Clara, CA, USA). This material was further fragmented to 300–800 base pairs using a Covaris E220 (Covaris, Woburn, MA, USA), and processed using Complete Genomics' proprietary standard library construction [5]. For LFR libraries, approximately 5 cells were collected and deposited into a 1.5 ml microtube with 10 μ l of distilled water. Cells were lysed, and DNA was denatured using 1 μ l of 20 mM KOH and 0.5 mM EDTA. Denatured genomic DNA was dispersed across a 384-well plate. In each well, long genomic fragments (~40 kb) were amplified, fragmented, and tagged with a unique barcode adapter as previously described [3].

All libraries were sequenced using Complete Genomics' nanoarray sequencing platform [5].

BT-474 genome analysis

Read data of 343, 298, and 261 Gb from the STD, LFR1, and LFR2 libraries, respectively, were mapped to the NCBI human reference genome (build 37) using Complete Genomics' pipeline [3, 5, 6] (Table 1), resulting in close to ~100X coverage in each of the libraries. The high coverage allowed more than 90 % of the genome and exome of each library to be called (Table 1.). Plotting reads falling within 100 kb consecutive windows for the BT-474 standard library

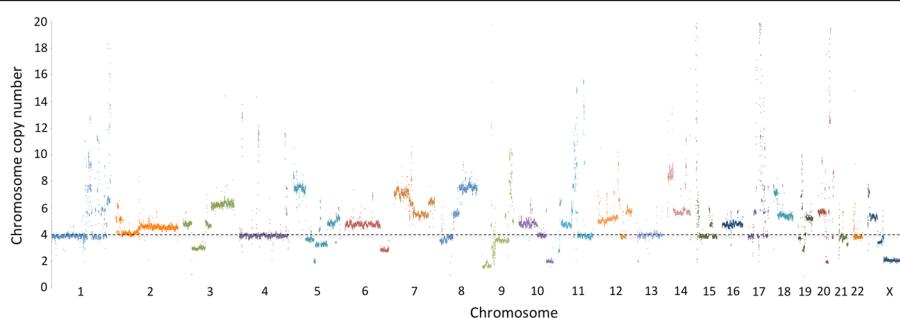

Fig. 1 100 kb read coverage. For the standard library of BT-474 reads were averaged across consecutive 100 kb bins, normalized to a tetraploid copy number, and plotted such that each dot represents the coverage of a single 100 kb region of the genome. Y-axis shows haploid copy number; x-axis shows genome position increasing from left to right for chromosome and position

All potential translocations identified in each library are listed. Translocations were clustered by 5 kb windows around the breakpoints to allow for comparison between different libraries. An explanation of the fields are as follows: SV ID, this is the ID for each translocation after clustering; chrA, the chromosome for the A side of the translocation; chrA start, the start of the breakpoint region for the chrA side; chrA end, the end of the breakpoint region for the chrA side; chrB, the chromosome for the B side of the translocation; chrB start, the start of the breakpoint region for the chrB side; chrB end, the end of the breakpoint region for the chrB side; breakpoint orientation, the direction of the translocation on each side of the translocation as compared to NCBI reference genome build 37, "f" represents the forward direction and "r" represents the reverse direction, the first letter is the chrA region and the second letter is the chrB region; library, the library for which each individual translocation was found

resulted in the expected complex pattern of amplifications affecting almost all chromosomes [2] (Fig. 1). Known amplifications of ERBB2 and the HOX gene cluster on chromosome 17 [2] are readily identifiable from this plot, as well as many other megabase-sized highly amplified regions. Analysis of both standard and LFR libraries resulted in the discovery of 110, 175, and 145 interchromosomal translocations in the STD, LFR1, and LFR2 libraries, respectively (Table 2). Clustering these translocations, based on windows of 5 kb around the breakpoints, led to the overlap of many translocations within and between libraries, and an overall reduction in the total number of translocations to 291 (Table 2 and Fig. 2). Additionally, comparing our results to a published RNA sequencing

analysis of BT-474 [7, 8] demonstrated that three of the five coding interchromosomal translocations were called in our data (Table 3). In the remaining two translocations that were not called by our algorithms, raw reads were found to support their existence in our libraries; for the *STARD3-DOK5* translocation, improved algorithms would most likely detect this event. In the case of the *TRPC4AP-MRPL45* translocation only one mate pair read in the STD library was found in support, making it unlikely to have been called even with modifications to our algorithms.

Single nucleotide variants (SNVs) numbering 3.24 million were called in the STD library, and over 2.85 million in each of the LFR libraries. Of these, 2.84 million were called in all libraries (Fig. 3), demonstrating

good reproducibility between different methods of library construction. For all libraries the ratio of heterozygous to homozygous was close to 1; a ratio much lower than the expected ~1.6 for Caucasian genomes. This is most likely the result of loss of heterozygosity (LOH) from the deletion or multi-copy amplifications of large portions, and/or the complete parental copy

of almost all chromosomes in the BT-474 genome, as seen in our data (Fig. 1 and Fig. 4), and as previously described [2]. This was confirmed by estimating what would happen to heterozygous variants in the NA12878 genome (the sample used by the ‘Genome in a Bottle’ Consortium [9]) in two scenarios: if the same percentage of the genome was LOH based on 1) the percentage of the genome lost, or 2) the percentage of variants lost (22.2 % and 20.3 %, respectively, Table 4). In both cases the ratio of heterozygous to homozygous variants was reduced to close to 1 (Table 5).

Analysis of the coding regions of a comprehensive list of known cancer-causing genes [10, 11] identified 67 small variants (<50 base pairs, Additional file 1). Most of these are probably inherited variants with no involvement in tumor formation, however variants in *TP53* and *PIK3CA*, previously found as somatic mutations in many tumors [12], were found in this cell line (Additional file 1). Also identified in our data: a potentially inherited variant in *CHEK2*, listed as ‘likely to be pathogenic’ in the ClinVar database [13]. To demonstrate the quality of our variant calls we compared them to a list generated by targeted sequencing of BT-474 as part of the Cancer Cell Line Encyclopedia (CCLE) project [14]. When the data from all three libraries were combined, 92 % of the variants found in CCLE were also called in our data, suggesting that our BT-474 genome is of good quality (Fig. 5 and Additional file 2). Further, 130 variants were found in two or more of our libraries that were not found in the CCLE data. This is either because the exons in which these variants were found were not covered as part of the CCLE target set, these variants were missed in the CCLE sequencing analysis, or to a lesser extent they are false positives in our dataset (Additional file 2).

Table 3 Translocations confirmed by published RNA sequencing data

ChrA	GeneA	ChrA start	ChrA end	GeneA strand	ChrB	GeneB	ChrB start	ChrB end	GeneB strand	Paper	Supported by SV data	Supported by raw reads
1	AHCTF1	247,002,400	247,094,726	-	4	NAAA	76,831,808	76,862,166	-	Kangaspeska et al.	yes SV_ID37	yes
17	STARD3	37,793,333	37,820,454	+	20	DOK5	53,092,266	53,267,710	+	Edgren et al.	no	yes
20	VAPB	56,964,175	57,026,157	+	17	IKZF3	37,913,968	38,020,441	-	Edgren et al.	yes SV_ID124	yes
20	TRPC4AP	33,590,207	33,680,618	-	17	MRPL45	36,452,989	36,479,101	+	Kangaspeska et al.	no	yes
20	RAB22A	56,884,771	56,942,563	+	19	MYO9B	17,186,591	17,324,104	+	Edgren et al.	yes SV_ID145	yes

Translocations identified in the standard and LFR libraries were compared to RNA sequencing identification of translocations in BT-474 from publications of Edgren et al. [7] and Kangaspeska et al. [8]. An explanation of the fields are as follows: chrA, the chromosome for the A side of the translocation; geneA, the gene affected on the A side of the translocation; chrA start, the start of the breakpoint region for the chrA side; chrA end, the end of the breakpoint region for the chrA side; geneA strand, the coding direction of the gene on the A side of the translocation; chrB, the chromosome for the B side of the translocation; geneB, the gene affected on the B side of the translocation; chrB start, the start of the breakpoint region for the chrB side; chrB end, the end of the breakpoint region for the chrB side; geneB strand, the coding direction of the gene on the B side of the translocation; paper, the publication in which the translocation was identified; supported by SV data (if there is evidence from at least one of our libraries to support this translocation a “yes” will appear in the table followed by the SV ID for our translocation, otherwise a “no” will appear); supported by raw reads (if there is evidence from at least one mate-pair read in one of our libraries to support this translocation a “yes” will appear in the table followed by the SV ID for our translocation, otherwise a “no” will appear)

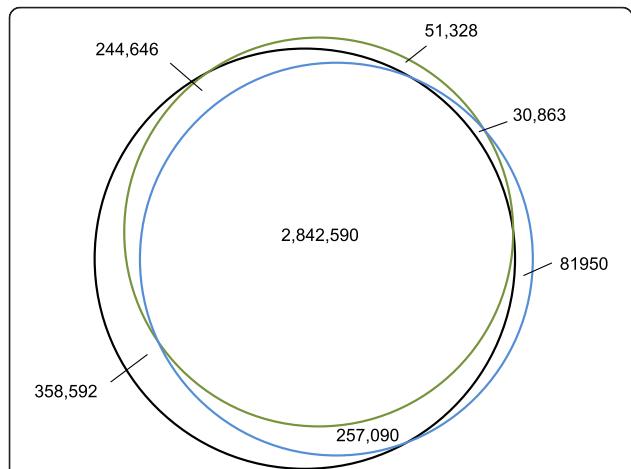

Fig. 3 Overlap of called variations between libraries. Single nucleotide variants (SNVs) numbering 3.24 million were called in the STD library, and over 2.85 million in each of the LFR libraries. The overlap between each library was compared and plotted. The standard library (black), and LFR libraries 1 (blue) and 2 (green) are highly overlapping, demonstrating that the majority of the variant calls are highly reproducible between separately processed sequencing libraries

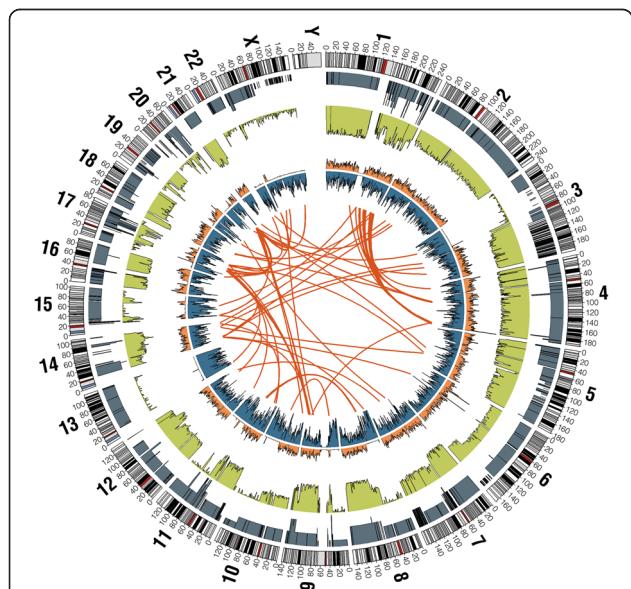

Fig. 4 Circos plot of the BT-474 genome. Chromosome number (in large bold numbers and letters), chromosome position (in small numbers), and a karyotype ideogram form the outer circle of the plot. The remaining circles are described in order of outermost to innermost: called ploidy (the copy number of region; blue-gray), Lesser Allele Fraction (LAF, the fraction of the lesser allele, 0.5 for a heterozygous SNP, 0 for a homozygous SNP; green), density of heterozygous SNPs (orange), and density of homozygous SNPs (blue). Lines in the center of the plot represent interchromosomal junctions

Availability of supporting data

Complete Genomics data formats

The entire data set from Complete Genomics, provided here, consists of a series of files and directories covering various categories of whole genome analysis (Fig. 6). A complete description of all files and the methods used to generate them can be found in the “Standard Sequencing Service Data File Formats v2.5” document provided by Complete Genomics, Inc. (available in Additional file 3 [15]).

LFR-specific files

Data packages from LFR do not include directories for structural variation (SV) or mobile element insertion (MEI; for more information on the content of these directories see the “Standard Sequencing Service Data File Formats v2.5” file mentioned above. In addition, one of the fields in the variant file (hapLink) is modified and there are six new fields described below:

- **hapLink:** LFR phased variants have an ID with the pattern: “Phased_#_#_#”, where # is an integer, the first two #s describe unique contigs, and the last # in the series is either 1 or 0 and represents the two possible haplotypes for each contig. All SNPs sharing the same “Phased_#_#_#” are from the same haplotype.
- **wellCount:** total number of LFR wells (out of 384) containing sequence reads calling the variant or reference allele. This metric is used to identify polymerase-induced false positive calls, since it is unlikely that random polymerase errors will occur in multiple different wells. A complete explanation of this concept can be found in Peters et al. [4].
- **wellIDs:** contains the IDs of the specific wells from which reads calling the variant come.
- **exclusiveWellCount:** this is the number of wells at each locus that have reads calling only the variant or the reference allele (not both). For true heterozygous variants this number should be close to that obtained for “wellCount”.
- **SharedWellCount:** at each locus this is the number of wells that contain reads calling both alleles. For true heterozygous variants this should be low; having a high number here suggests mapping errors. For homozygous variants almost all of the well counts should be in this field.
- **MinExclusiveWellCountInThisLocus:** this is the minimum number of exclusive wells (non-shared well counts) at each locus.
- **MaxExclusiveWellCountInThisLocus:** this is the maximum number of exclusive wells (non-shared well counts) at each locus.

Table 4 Calculation of the amount of LOH in BT-474

Chromosome	Base pairs	Variations	Centromere position (Mbp)	% LOH	LOH (bp)	LOH (variations)
1	249,250,621	4,401,091	125	0.0 %	0	0

15	102,531,392	1,577,346	19	75.0 %	76898544	1183010
16	90,354,753	1,747,136	36.6	0.0 %	0	0
17	81,195,210	1,491,841	24	0.0 %	0	0
18	78,077,248	1,448,602	17.2	0.0 %	0	0
19	59,128,983	1,171,356	26.5	0.0 %	0	0
20	63,025,520	1,206,753	27.5	0.0 %	0	0
21	48,129,895	787,784	13.2	0.0 %	0	0
22	51,304,566	745,778	14.7	100.0 %	51304566	745778
X	155,270,560	2,174,952	60.6	100.0 %	155270560	2174952
Total	3,036,303,846	55,470,937	1,028		674,184,811	11,250,331
% of total in LOH					22.2 %	20.3 %

Loss of heterozygosity (LOH) in the genome of BT-474 was calculated based on the genomic distance covered by large areas (>10 mb), where the lesser allele fraction is zero. In our data the lesser allele was calculated in 100 kb windows, based on read counts at all fully called variant loci. An explanation of the fields are as follows: chromosome, the chromosome for which each LOH region was calculated; base pairs, the total number of base pairs for each chromosome based on the NCBI reference genome build 37; variations, total number of confirmed variations for each chromosome based on Ensembl genome browser release 68; centromere position (Mbp), the location in megabases of the centromere for each chromosome; %LOH, the percentage of each chromosome estimated to have LOH; LOH (bp), the total number of base pairs for each chromosome that are estimated to be found in LOH regions; the total number of variations from Ensembl genome browser release 68 that are found within the estimated LOH region

Table 5 NA12878 simulation of LOH event in BT-474

	Variants in NA12878	Variants based on LOH simulation by length	Variants based on LOH simulation by number of variations
Hom SNPs	1,306,544	1,768,557	1,729,016
Het SNPs	2,081,141	1,619,128	1,658,669
Ratio	1.59	0.92	0.96

The percentage of the BT-474 genome found to be in regions of LOH was used to simulate what would happen to the heterozygous and homozygous variants in the genome of NA12878 if that same amount of LOH was to occur. The simulation demonstrated that the LOH variants, and the increase in homozygous variants as a result, caused a shift in the Het/Hom SNP ratio from 1.59 to 0.92–0.96, similar to the average ratio of the three libraries of 0.98 seen in BT-474. An explanation of the fields are as follows: hom SNPs, total number of homozygous variants; het SNPs, total number of heterozygous variants; variants in NA12878, number of variants of each category in the genome of NA12878; variants based on LOH simulation by length, the change in the number of variants based on applying the percentage of LOH as calculated from the total length of the LOH region in BT-474; variants based on LOH simulation by number of variations, the change in the number of variants based on applying the percent of LOH as calculated from the total number of variants in the LOH region in BT-474

LFR structural variant analysis files

Each LFR genome contains an LFR-specific structural variant file in the ASM directory (see Fig. 2 for directory tree). This file is generated using a novel algorithm that identifies unexpected mate-pairs that are found in more than one compartment of an LFR library (manuscript in preparation). A full description of the headers can be found within each file under the Excel tab labeled “Header Description”.

Read and mapping data for all genomes reported here are available at the European Nucleotide Archive (ENA) under study accession number PRJEB10587. Sample accession numbers for each sequence library can be found in Table 1. Supporting data is also available from the *GigaScience GigaDB* database [16].

Additional files

Additional file 1: Cancer-associated genes with variants in BT-474. (PDF 123 kb)

Additional file 2: Comparison of calls to CCLE. (PDF 1347 kb)

Additional file 3: Standard Sequencing Service Data File Formats v2. (PDF 6212 kb)

LFR: Long Fragment Read technology; STD: Complete genomics standard library; SV: Structural variations; ENA: European Nucleotide Archive; SKY: Spectral karyotype; SNV: Single nucleotide variant; CCLE: Cancer Cell Line Encyclopedia.

Competing interests

The authors are shareholders in BGI holdings and Complete Genomics. BGI derives income from whole genome sequencing.

Authors' contributions

BAP, SJL, and RD conceived the study. RYZ and RC cultured cells, isolated genomic DNA, and generated all of the sequencing libraries. SC, NG, QM, and ZL processed and analyzed the data. All authors read and approved the final manuscript.

Acknowledgements

We would like to acknowledge the ongoing contributions and support of all Complete Genomics employees, in particular the many highly skilled individuals working in the libraries, reagents, and sequencing groups, who make it possible to generate high quality whole genome data.
